

## PROBLEM HEARTS

LITTLE GREEN HEART has gifted LITTLE PURPLE HEART for Valentine's Day two arrays  $A$  and  $B$  of size  $N$  which together contain the numbers from 1 to  $2 \times N$  exactly once.

LITTLE PURPLE HEART performs the following operation:

1. She chooses 2 indices  $l$  and  $r$  with  $1 \leq l \leq r \leq N$ .
2. She creates an array  $C$  of size  $k = r - l + 1$ , such that for every  $i$  with  $0 \leq i < k$  she chooses either  $C_i = A_{l+i}$  or  $C_i = B_{l+i}$ .
3. She calculates the value  $\text{val}(C)$ , which is equal to the number of indices  $i$  with  $0 \leq i < k$  such that there is no index  $j$  with  $0 \leq j < i$  and  $C_j > C_i$ .

LITTLE GREEN HEART, being the computer scientist that he is, wants to impress LITTLE PURPLE HEART by computing the sum of  $\text{val}(C)$  for all the arrays  $C$  that she could have constructed. Since this number can be quite large, he wants to compute it modulo  $10^9 + 7$ . Moreover, he wants to do so for  $Q$  different operations.

Formally, given  $Q$  queries of the form  $(l, r)$ ,  $1 \leq l \leq r \leq N$ , he defines  $S$  as the set of all the arrays  $C$  that LITTLE PURPLE HEART could have built. Then, for each query, he wants to calculate

$$P(l, r) = \sum_{C \in S} \text{val}(C) \pmod{10^9 + 7}$$

Your task is to help LITTLE GREEN HEART impress LITTLE PURPLE HEART by computing the answer to each query.

**INPUT DATA** The first line of the input contains the number  $N$ . The second line contains  $N$  numbers  $A_1, A_2, \dots, A_n$  representing the array  $A$ . The third line contains  $N$  numbers  $B_1, B_2, \dots, B_n$  representing the array  $B$ . Together, these 2 arrays contain the numbers from 1 to  $2 \times N$  exactly once.

The fourth line contains the number of queries  $Q$ . Each of the following  $Q$  lines contains 2 numbers describing a query of the form  $l \ r$ .

**OUTPUT DATA** The output should contain  $Q$  lines representing the answers to all queries  $P(l, r)$ , each on a new line, computed modulo  $10^9 + 7$ .

**RESTRICTIONS**

- ◆  $1 \leq N \leq 70\,000$ .
- ◆  $1 \leq Q \leq 70\,000$ .

| # | Points | Constraints  |
|---|--------|--|
| 1 | 5      | $1 \leq N \leq 17, 1 \leq Q \leq 100$              |
| 2 | 16     | $1 \leq N, Q \leq 300$                             |
| 3 | 9      | $B_i = A_i + 1$ for all $i$ with $1 \leq i \leq N$ |
| 4 | 17     | $1 \leq N, Q \leq 10\,000$                         |
| 5 | 11     | $1 \leq Q \leq 200$                                |
| 6 | 14     | $1 \leq N \leq 50\,000, 1 \leq Q \leq 10\,000$     |
| 7 | 10     | $1 \leq N, Q \leq 50\,000$                         |
| 8 | 18     | No further restrictions                            |

## EXAMPLES

| Input data                      | Output data |
|---------------------------------|-------------|
| 6                               | 37          |
| 2 10 3 4 5 6                    | 5           |
| 11 1 9 8 7 12                   |             |
| 2                               |             |
| 3 6                             |             |
| 1 2                             |             |
| 12                              | 32          |
| 11 10 7 23 1 18 22 16 8 14 20 6 |             |
| 3 4 9 13 19 5 24 12 15 21 17 2  |             |
| 1                               |             |
| 7 11                            |             |

## EXPLANATIONS

**First example.** There are 2 queries.

For the first query, we will consider the subsequences  $A_3, A_4, A_5, A_6$  and  $B_3, B_4, B_5, B_6$  when constructing  $C$ . Next we consider all possible options for  $C$  and sum  $\text{val}(C)$ . For example, for  $C = [3, 8, 7, 12]$ , the indexes  $i = 0, 1, 3$  have the property that there is no  $0 \leq j < i$  such that  $C_j > C_i$ . Therefore,  $\text{val}(C) = 3$ .

Summing  $\text{val}(C)$  across all arrays  $C$  that can be constructed, we get  $P(3, 6) = 37$ .

For the second query, we can construct 4 arrays  $C$ :

$$P(1, 2) = \text{val}([2, 10]) + \text{val}([2, 1]) + \text{val}([11, 10]) + \text{val}([11, 1]) = 2 + 1 + 1 + 1 = 5.$$

**Second example.** There is one query. Computing  $P(7, 11) = 32$ .
